① Introduction

② The plan

③ Classifying space

④ Discrete manifolds

⑤ Connections and curvature

⑥ Results

Motivation

The motivation is to provide a deeper explanation for Chern-Weil theory by finding connections and curvature in HoTT principal bundles.

- Construct a classifying space of principal bundles
- Construct a type of manifolds
- Identify connections and curvature
- Put these to use in 2-d to prove that total curvature is an integer

Definition

Let G be a group with identity element e . A G -**set** is a set X equipped with a homomorphism $\phi : (G, e) \rightarrow \text{Aut}(X)$. If we have

$$\text{is_torsor}(X, \phi) \stackrel{\text{def}}{=} \|X\|_{-1} \times \prod_{x:X} \text{is_equiv}(\phi(-, x) : (G, e) \rightarrow (X, x))$$

we say (X, ϕ) is a G -**torsor**. Denote the type of G -torsors by BG .

Lemma

Point BG at G_{reg} , the G -torsor G acting on itself on the right. Then $\Omega_{G_{\text{reg}}} BG \simeq G$, so BG is a $K(G, 1)$.

Definition

$$\mathrm{EM}(G, n) \stackrel{\mathrm{def}}{=} \mathrm{BAut}(K(G, n)) \stackrel{\mathrm{def}}{=} \sum_{Y:\mathcal{U}} \|Y \simeq K(G, n)\|_{-1}$$

Definition

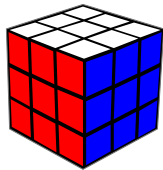

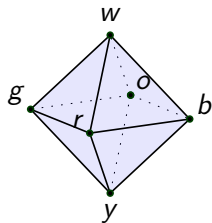

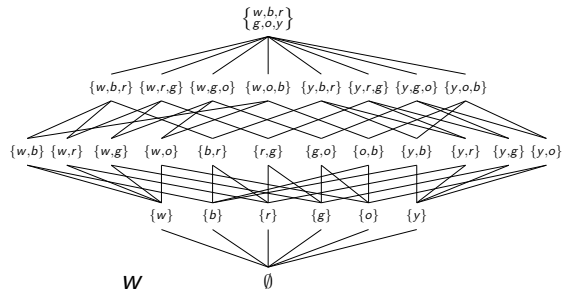

A $K(G, n)$ -**bundle** on a type M is a map $f : M \rightarrow \mathrm{EM}(G, n)$.

We further assume f factors through $K(G, n+1)$ and so is principal.

Discrete manifolds in HoTT

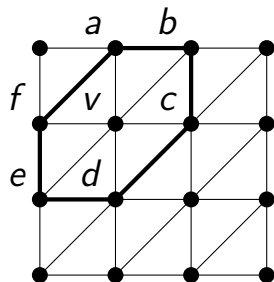

- Recall the classical theory of **simplicial complexes**
- Define a **realization** functor via higher inductive types (pushouts)

Simplicial complexes

A **Hasse diagram** of a simplicial complex (vertices named for the colors on a Hungarian Cube)

Higher realization

The **link** of a vertex v in an n -complex is the $(n - 1)$ -subcomplex of faces not containing v but whose union with v is a face.

This will be our model of the tangent space.

Higher realization

$$\begin{array}{ccc}
 M_1 \times \partial\Delta^1 & \xrightarrow{\text{pr}_1} & M_1 \\
 \mathbb{A}_0 \downarrow & \nearrow h_1 \lrcorner & \downarrow *M_1 \\
 M_0 = \mathbb{M}_0 & \longrightarrow & \mathbb{M}_1
 \end{array}$$

Form a pushout of edges to create a 1-type.

$$\begin{array}{ccccc}
 & & M_2 \times \partial\Delta^2 & \xrightarrow{\text{pr}_1} & M_2 \\
 & & \mathbb{A}_1 \downarrow & \nearrow h_2 \lrcorner & \downarrow *M_2 \\
 \mathbb{M}_0 & \longrightarrow & \mathbb{M}_1 & \longrightarrow & \mathbb{M}_2 \\
 \mathbb{A}_0 \uparrow & & \lrcorner \uparrow & & \uparrow *M_1 \\
 & \searrow h_1 & & & \\
 M_1 \times \partial\Delta^1 & \xrightarrow{\text{pr}_1} & M_1 & &
 \end{array}$$

Then push out maps from a 1-type triangle to from a 2-dim type.

Carnegie Mellon University

Higher realization

$$\begin{array}{ccccc}
 & & M_2 \times \partial\Delta^2 & \xrightarrow{\text{pr}_1} & M_2 \\
 & & \downarrow \mathbb{A}_1 & \nearrow h_2 & \downarrow *_{M_2} \\
 M_0 & \longrightarrow & M_1 & \longrightarrow & M_2 \\
 \uparrow \mathbb{A}_0 & & \uparrow *_{M_1} & & \downarrow \lrcorner \\
 M_1 \times \partial\Delta^1 & \xrightarrow{\text{pr}_1} & M_1 & &
 \end{array}$$

$*_{M_1}, *_{M_2}$ provide **hubs**.

h_1, h_2 provide **spokes**.

Definition

An n -gon $\mathbb{C}(n)$ is the realization of a complex $C(n)$:

$$C(n)_0 = \{v_1, \dots, v_n\}$$

$$C(n)_1 = \{e_1 = \{v_1, v_2\}, \dots, e_{n-1} = \{v_{n-1}, v_n\}, e_n = \{v_n, v_1\}\}$$

Toss in the non-complexes

$$\mathbb{C}(1) \stackrel{\text{def}}{=} S^1, \quad \mathbb{C}(2) \stackrel{\text{def}}{=} \ell_{12} \begin{array}{c} v_1 \\ \circ \\ \text{---} \\ \circ \\ v_2 \end{array} r_{21}$$

We sometimes denote a polygon with vertices $\{a, b, c\}$ with $[abc]$, its realization with $\llbracket abc \rrbracket$.

Lemma

$\mathbb{C}(2) \simeq \mathbb{C}(1)$ and in general $\mathbb{C}(n) \simeq \mathbb{C}(n - 1)$.

Corollary

All n -gons are equivalent to S^1 and so provide terms in $\text{EM}(\mathbb{Z}, 1)$.

Rotation

Let $R : [abcd] \rightarrow [abcd]$ send $a \mapsto b, b \mapsto c, c \mapsto d, d \mapsto a$.

Extend R to edges.

Lemma

$\llbracket R \rrbracket : \llbracket abcd \rrbracket \rightarrow \llbracket abcd \rrbracket$ is homotopic to the identity, i.e. we have $\prod_{x:\llbracket abcd \rrbracket} x = \llbracket R \rrbracket(x)$.

Proof.

Use edges. □

Definition

If $\mathbb{M} \stackrel{\text{def}}{=} \mathbb{M}_0 \xrightarrow{\iota_0} \dots \xrightarrow{\iota_{n-1}} \mathbb{M}_n$ is a cellular type and all the triangles commute in the diagram:

$$\begin{array}{ccccccc}
 \mathbb{M}_0 & \xrightarrow{\iota_0} & \mathbb{M}_1 & \xrightarrow{\iota_1} & \mathbb{M}_2 & \xrightarrow{\iota_2} & \dots \xrightarrow{\iota_{n-1}} \mathbb{M}_n \\
 & & \searrow f_0 & \searrow f_1 & \downarrow f_2 & & \swarrow f_n \\
 & & & & \mathcal{U} & &
 \end{array}$$

- The map f_k is a **k -bundle** on \mathbb{M} .
- The pair given by the map f_k and the proof $f_k \circ \iota_{k-1} = f_{k-1}$, i.e. that f_k extends f_{k-1} is called a **k -connection on the $(k-1)$ -bundle f_{k-1}** .

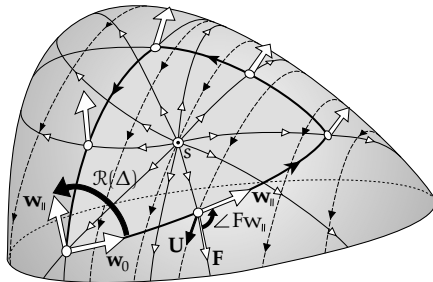

Definition

If \mathbb{M} is the realization of a simplicial complex and we have

$$\begin{array}{ccc}
 M_k \times \partial\Delta^k & \xrightarrow{\text{pr}_1} & M_k \\
 \mathbb{A}_{k-1} \downarrow & \nearrow h_k & \downarrow * \mathbb{M}_k \\
 \mathbb{M}_{k-1} & \xrightarrow{v_{k-1}^\perp} & \mathbb{M}_k \\
 & \searrow f_{k-1} & \downarrow f_k \\
 & & \mathcal{U}
 \end{array}
 \qquad
 \begin{array}{ccc}
 \{m_k\} \times \partial\Delta^k & \xrightarrow{!} & \mathbf{1} \\
 \mathbb{A}_{k-1} \downarrow & \swarrow b_k & \downarrow * \mathbb{M}_k \\
 \mathbb{M}_{k-1} & \longrightarrow & \mathcal{U}
 \end{array}$$

then we say the filler b_k is called a **flatness structure for the face** m_k , and its ending path is called **curvature at the face** m_k .

Classical proof

[26.2] The difference $\mathcal{R}(\Delta) - 2\pi \mathcal{I}_F(s)$ can be found by summing over the edges K_j the change $\Phi(K_j)$ in the illustrated angle $\angle Fw_{||}$, i.e., the rotation of $w_{||}$ relative to F .

- The classical proof is discrete-flavored.
- “ $\angle Fw_{||}$ ” looked a lot like a pathover.
- Hopf’s Φ is defined on edges, not loops. We imitated that too.
